Abstract. Submission systems ask for the same author details again and again. We split each manuscript into zones and read authors only from the header, which stops cited authors from leaking into the result.

Keywords: metadata · zone segmentation · author linking

1 Introduction

Large language models are now used to read scientific documents, yet most submission systems still ask authors to type the same metadata by hand. Prior work by Smith et al. [3] studied header parsing with conditional random fields, while Lee and Wong [5] relied on font statistics. We compare layout rules with learned models on manuscripts from many templates and report where each one fails.
